

**METHOD FOR MAKING ELECTRONIC DEVICES INCLUDING SILICON
AND LTCC AND DEVICES PRODUCED THEREBY**

Field of the Invention

The present invention relates to the field of electronic devices and manufacturing methods, and, more particularly, to methods for making and devices such as
5 including packaged integrated circuits.

Background of the Invention

Integrated circuits are widely used in many types of electronic equipment. An integrated circuit may include a silicon substrate in which a number of active
10 devices, such as transistors, etc., are formed. It is also typically required to support one or more such integrated circuits in a package that provides protection and permits external electrical connection.

As the density of active devices on typical
15 integrated circuits has increased, dissipation of the heat generated has become increasing more important. Designers have developed cooling techniques for integrated circuits based on micro-electromechanical (MEMs) technology.

20 For example, as shown in FIG. 1, a prior art electronic device **10** includes a package **11** including a first member **12** comprising silicon, and a second member **14** comprising a low temperature co-fired ceramic (LTCC)

material. The first member **12** may include several stacked silicon substrates **12a**, **12b** having various components of a micro-fluidic cooler formed therein. For example, as shown in the illustrated embodiment, an
5 evaporator **16** and condensor **17** may be provided and interconnected via one or more micro-fluidic channels or passageways **21** formed between the silicon substrates **12a**, **12b**. One or more MEMs pumps, not shown, may circulate the cooling fluid.

10 The second member **14** may also include several LTCC layers **14a**, **14b** laminated together as shown in the illustrated embodiment. The second member **14** also illustratively carries an integrated circuit **22**, such as an insulated gate bipolar transistor (IGBT) or other
15 integrated circuit that may typically generate substantial waste heat. The second member **14** also includes external connections **23** which are connected to the electrical connections **24** of the integrated circuit **22** via the illustrated wires **25**.

20 As shown in the enlarged view of FIG. 2, the integrated circuit **22** is carried by a receiving recess **27** in the second member **14**. A series of micro-fluidic passageways **30** may be provided through the LTCC member **14** adjacent the integrated circuit **22** to deliver
25 cooling fluid thereto.

Typically, the LTCC member **14** and the silicon member **12** are adhesively joined together as schematically illustrated by the adhesive layer **31**. Thermoplastic and/or thermosetting adhesives are
30 commonly used. Metal layers may also be used. Unfortunately, the adhesive layer **31** has a number of shortcomings. The adhesive layer **31** may not typically provide a hermetic seal at the interface between the

silicon and LTCC, thus, cooling fluid may be lost. In addition, the adhesive layer **31** may also provide yet another layer through which the heat must pass. Of course, it may be difficult to provide an adhesive
5 layer **31** which is uniform and which does not protrude into the interface or otherwise block or restrict the flow of cooling fluid. In other words, such an adhesive layer **31** unfortunately provides only non-hermetic and non-uniform bonding the members.

10 U.S. Patent No. 5,443,890 to Ohman discloses a leakage resistant seal for a micro-fluidic channel formed between two adjacent members. A sealing groove is provided and filled with a fluid sealing material which is compressed against adjacent surface portions
15 of the opposing member. The provision for such a sealing structure requires additional manufacturing steps and may not be suitable for many applications.

Summary of the Invention

In view of the foregoing background, it is
20 therefore an object of the invention to provide a method and associated electronic device wherein LTCC and silicon members are bonded together to form a hermetic seal with uniform bonding.

This and other objects, features and advantages in
25 accordance with the present invention are provided by a method for making an electronic device comprising positioning first and second members so that opposing surfaces thereof are in contact with one another, the first member comprising silicon and the second member
30 comprising a low temperature co-fired ceramic (LTCC) material. The method also includes anodically bonding together the opposing surfaces of the first and second members to form a hermetic seal therebetween. The

anodic bonding provides a secure and uniform bond between the members.

The first and second members may have substantially planar major opposing surfaces. The
5 anodic bonding provides a uniform bond across these surfaces to reduce possible stress effects which may otherwise occur due to the difference in thermal coefficients of expansion of the two different materials.

10 Anodically bonding may comprise applying a voltage across the first and second members, applying pressure to the opposing surfaces of the first and second members, and/or heating the first and second members. The method may also include cleaning the opposing
15 surfaces of the first and second members prior to anodically bonding the members.

The method may further include forming at least one cooling structure in at least one of the first and second members. More particularly, the least one
20 cooling structure may comprise at least one first micro-fluidic cooling structure in the first member, and at least one second micro-fluidic cooling structure in the second member aligned with the at least one first micro-fluidic cooling structure. The at least
25 one first micro-fluidic cooling structure may comprise an evaporator and the at least one second micro-fluidic cooling structure may comprise at least one micro-fluidic passageway. Anodic bonding permits a hermetic seal between the two members, and significantly reduces
30 or eliminates the loss of cooling fluid at the interface between the two members which could otherwise occur.

The method may also include positioning at least one integrated circuit adjacent the at least one
35 cooling structure, such as adjacent the at least one

micro-fluidic cooling passageway in the second member. The at least one integrated circuit may comprise electrical connections, and the second member may carry external electrical connections connected to the
5 electrical connections of the at least one integrated circuit.

For typical electronic devices, the anodically bonding may comprise applying a voltage in a range of about 500 to 1000 volts across the first and second
10 members. Similarly, the anodically bonding may comprise applying pressure in a range of about 1 to 20 psi to the opposing surfaces of the first and second members. Continuing along these lines, the anodically bonding may comprise heating the first and second
15 members to a temperature in a range of about 100 to 150°C.

Another aspect of the invention relates to an electronic device, such as a multi-chip module (MCM) or other similar packaged integrated circuit, for example.
20 The electronic device may comprise a first member comprising silicon, and a second member comprising a low temperature co-fired ceramic (LTCC) material. Moreover, the first and second members have opposing surfaces thereof anodically bonded together to form a
25 hermetic seal therebetween. The first and second members may have opposing generally planar major opposing surfaces, for example.

At least one of the first and second members may comprise at least one cooling structure. For example,
30 the first member may comprise at least one first micro-fluidic cooling structure therein, such as an evaporator. In addition, the second member may further comprise at least one second micro-fluidic cooling structure aligned with the at least one first micro-
35 fluidic cooling structure of the first member. For

example, the at least one second micro-fluidic cooling structure may comprise at least one micro-fluidic passageway.

The electronic device may also include at least one integrated circuit adjacent the at least one second micro-fluidic cooling structure of the second member. The at least one integrated circuit may also comprise electrical connections. Accordingly, the second member may comprise external electrical connections connected to the electrical connections of the at least one integrated circuit.

Brief Description of the Drawings

FIG. 1 is a schematic cross-sectional view of an electronic device according to the prior art.

FIG. 2 is a greatly enlarged view of a portion of the electronic device as shown in FIG. 1.

FIG. 3 is a schematic cross-sectional view of an electronic device in accordance with the present invention.

FIG. 4 is a greatly enlarged portion of the electronic device as shown in FIG. 3.

FIG. 5 is a schematic diagram of the electronic device as shown in FIG. 3 being made in an apparatus in accordance with the invention.

FIG. 6 is a schematic diagram of the anodic bond interface as in the electronic device shown in FIG. 3.

FIG. 7 is a flowchart illustrating the method in accordance with the present invention.

Detailed Description of the Preferred Embodiments

The present invention will now be described more fully hereinafter with reference to the accompanying drawings in which preferred embodiments of the invention are shown. This invention may, however, be

embodied in many different forms and should not be construed as limited to the illustrated embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

Referring now initially to FIGS. 3-7 the electronic device and method for making the device in accordance with the invention are now described. In particular, as shown in FIGS. 3 and 4, an illustrated embodiment of an electronic device **110** in accordance with the invention is shown. The electronic device **110** differs from the prior art device shown in FIGS. 1 and 2 in that the conventional adhesive layer **31** is replaced by an anodically bonded interface **135** as will be described in greater detail herein.

The electronic device **110** illustratively mounts a single integrated circuit **122** in the package **111** although those of skill in the art will recognize that the invention is also applicable to other electronic devices as well. For example, the electronic device may also be an MCM, or other similar device including one or more integrated circuits **122** contained in a similar mounting package. The electronic device **110** illustratively includes a first member **112** comprising silicon, and a second member **114** comprising a low temperature co-fired ceramic (LTCC) material. The first and second members **112**, **114** have opposing surfaces thereof anodically bonded together to form a hermetic seal at the interface **135** therebetween.

As shown in the illustrated embodiment, the first and second members **112**, **114** have opposing generally planar major opposing surfaces being anodically bonded

together. At least one of the first and second members **112**, **114** may comprise at least one cooling structure therein as will be appreciated by those skilled in the art. For example, as shown in the illustrated
5 electronic device **110**, the first member **112** includes at least one first micro-fluidic cooling structure therein, such as the illustrated evaporator **116**.

The second member **114** may include at least one second micro-fluidic cooling structure aligned with the
10 at least one first micro-fluidic cooling structure of the first member **112**. For example, and as shown in the illustrated embodiment of the electronic device **110**, the at least one second micro-fluidic cooling structure may comprise at least one micro-fluidic passageway **130**.

15 The electronic device **110** also illustratively includes an integrated circuit **122** adjacent the micro-fluidic passageways **130** of the second member **114**. Of course, in other embodiments, more than one integrated circuit may be mounted within the package **111**. In
20 addition, an optical/electronic device may also be mounted and cooled as described herein as will be appreciated by those skilled in the art. The integrated circuit **122** also illustratively includes electrical connections **124** which are brought out to the
25 external electrical connections **123** using conventional techniques as will be appreciated by those skilled in the art.

As will also be appreciated by those skilled in the art, in other embodiments of the invention, the
30 integrated circuit **122** may include a back contact layer, not shown, which is also connected to an external electrical connector carried by the second member. In addition, the integrated circuit **122** may be

mounted using flip chip bonding techniques in other embodiments.

The other elements of the illustrated electronic device **110** of the invention are indicated with
5 reference numerals incremented by one hundred as compared to the similar elements of the electronic device shown in FIGS. 1 and 2. Accordingly, these common elements need no further discussion herein.

Referring now more particularly to FIGS. 5-7,
10 method aspects of the invention are now described in greater detail. The method is for making an electronic device **110**, such as described above. As seen in the flowchart of FIG. 7, from the start (Block **150**) the method may include cleaning and preparation of the
15 opposing surfaces of the first and second members **112**, **114** at Block **152**. Preparation may include polishing or other techniques to ensure that the surface roughness of each opposing surface is within a desired range.

At Block **154** the method includes positioning first
20 and second members **112**, **114** so that opposing surfaces thereof are in contact with one another. As described above, the first member **112** comprises silicon and the second member **114** comprises an LTCC material. At Block **156** the opposing surfaces of the first and second
25 members **112**, **114** are anodically bonding together.

Referring now briefly to the schematically illustrated apparatus **140** of FIG. 5 an embodiment of anodic bonding is further described. The first and second members **112**, **114** may be aligned between the top
30 electrode **142** and the bottom electrode **141** of the apparatus **140**. The bottom electrode **141** is also carried by a heated support **144**. A voltage source **143** is connected to the top and bottom electrodes **142**, **141**. The apparatus **140** can provide the necessary voltage,

pressure and temperature ranges for efficient anodic bonding of the first and second members **112, 114**.

For typical electronic devices such as the illustrated electronic device **110** or MCMs, for example, the voltage source **143** may apply a voltage in a range of about 500 to 1000 volts across the first and second members **112, 114**. Similarly, the apparatus may also apply a force such that the pressure between the opposing surfaces is in a range of about 1 to 20 psi. Additionally, the heated support may heat the first and second members **112, 114** to a temperature in a range of about 100 to 150°C. Of course, other voltages, pressures and temperatures are contemplated by the invention and may be used for other devices as will be appreciated by those skilled in the art. After the anodic bonding (Block **156**), the bonded first and second members **112, 114** may be cleaned and further processed before stopping (Block **160**).

As described above, the first and second members **112, 114** may have substantially planar major opposing surfaces, so that anodic bonding provides a uniform bond across these surfaces to reduce possible stress effects which may otherwise occur due to the difference in thermal coefficients of expansion of the two different materials. The anodic bonding provides a secure and uniform hermetic seal between the members **112, 114** and while overcoming the disadvantages described above resulting from using an adhesive.

The method may further include forming at least one cooling structure in at least one of the first and second members **112, 114**. These may be formed before or after anodic bonding, or they may be formed both before and after anodic bonding. The method may also include positioning at least one integrated circuit **122**

adjacent the at least one cooling structure, such as adjacent the at least one micro-fluidic cooling passageways **130** in the second or LTCC member **114**.

Anodic bonding advantageously provides a hermetic
5 seal between the two members, and significantly reduces or eliminates the loss of cooling fluid at the interface between the two members which could otherwise occur. It is believed without applicants wishing to bound thereto that the anodic bonding causes a
10 coordinate covalent matrix to form at the interface **135** between the first and second members **112, 114** as perhaps best shown in the schematic view of FIG. 6.

Many modifications and other embodiments of the invention will come to the mind of one skilled in the
15 art having the benefit of the teachings presented in the foregoing descriptions and the associated drawings. Accordingly, it is understood that the invention is not to be limited to the embodiments disclosed, and that other modifications and embodiments are intended to be
20 included within the spirit and scope of the appended claims.
